## Overview

What is the main issue with low frequency power inverters?

Low frequency power inverters suffer from a low frequency hum. This hum is caused by the fact that they use high speed power transistors to invert the DC to AC, but drive transistors at the same frequency (60 Hz or 50Hz) as the AC sine wave output.

What is a low frequency power inverter?

Low-frequency power inverters are commonly used in solar power generation systems and UPS uninterruptible power supplies in residential and commercial areas. Compared to high-frequency inverters, low-frequency power inverters have a purer output waveform and better stability, making them slightly more expensive.

How does a low frequency inverter work?

Low-frequency inverters operate by using a transformer to convert DC to AC at the utility frequency, typically 50 or 60 Hz. The presence of a transformer not only helps in stepping up or stepping down voltage but also provides galvanic isolation between the input and output, enhancing safety and reliability.

What is the difference between low frequency and high frequency inverters?

The low frequency inverters typically operate at ~60 Hz frequency. To produce a sine wave output, high-frequency inverters are used. These inverters use the pulse-width modification method: switching currents at high frequency, and for variable periods of time.
